## Tornado warning florida 2020

I'm originally from Florida, so I'm used to the fact that there are a lot of weird stuff. I don't think it was surprising to see that there were technically (comical) concerns about the possibility of anti-bestiality laws outlawing sex between people. Read the full article in the Huffington Post By Debbie Harbenick, Ph.D. is a sex researcher and educator, a widely read sex columnist, a widely read sex columnist, a female guide to sexual pleasure and satisfaction, a good person in a bed guide to preciously, and my lips read: a complete guide to vaginas and vruba. She is also the founder and editor .com mySexProfessor's website. Follow her and her Twitter@mysexprofessorand Facebook This content is created and maintained by third parties and imported to this page to help users provide their email addresses. piano.io Weather forecasters are warning of more storms to come following a devastating tornado in Oklahoma that killed at least 24 people. The Weather Channel's Kevin Ross predicts massive and catastrophic tornadoes from central or eastern Texas to Arkansas. Google has a crisis map showing the path of a tornado from the plains outside Oklahoma City to Moore. Survivors are being urged to sign in to the Red Cross Safety and Wells page, while Oklahoma City and state transportation officials have tweeted regular updates. #Oklahoma, #PrayForOklahoma and Red Cross were trending terms on Twitter Tuesday morning. A Facebook group has already been set up to help victims find belongings blown away by 200mph winds. The page's founder, Leslie Hegelberg, urges those who find documents and photos to take scans and photos and put them on the page so they can be returned to their rightful owners. Last year, a map was released showing more than half a century of U.S. tornadoes tracked by the N.O.A.A. Given that the brightest streaks on this map indicate the most powerful storms, yesterday's - one of the strongest in living memory - will certainly be one of the brightest when the map is updated. This profile is obtained from the QRIS Compendium and provides comprehensive information about all QRIS operating in the United States and the region. It was developed through build initiatives, early learning challenge collaboratives, and child trend partnerships. System planners in Miami-Dade County, Florida, established the Early Learning Career Center to increase staff education levels and stability before deploying QRIS. The Career Center manages scholarships for formal education and the state's Teacher Education and Compensation Assistance (T.E.A.C.H.) I was supplemented. Early childhood project funding; adjust wage\$ incentivesWe provided mobile carrier advisors to help gris program staff succeed in formal education. We maintained an online community training calendar. Professional development efforts were supported by a local registry that also announced a document repository for staff entitlement components in the evaluation system. Early childhood leaders in Miami, Florida, reported that the Web-based Early Learning System (WELS) data platform made Quality Counts QRIS stronger as it provided real-time feedback on participation, classroom profiles and assessments, professional development, technical assistance, coaching and mentoring, and other important data for a wide range of purposes. The data was available in certain programs as well as aggregations. This information allowed planners to have the data they needed and at the same time for program managers to receive alerts when one of the centers they were working on was not progressing in a timely manner. Izzy Schwartz/PhotoDisk/Getty Images Strong winds, hail and flying debris are dangerous to be in a tornado, but those who survive the experience claim to be surprisingly calm and quiet. Near-constant lightning reportedly gives the inside of the tornado a glow. The types of tornadoes are very different, so the experience can be very different. Water spouts that cross land are often much weaker than other tornadoes and can be too weak to bring people down. Supercell tornadoes, by contrast, usually contain many strong cyclones. These cyclones are dangerous, but there are relatively safe areas within the larger system, which is part of the reason why individual homes avoid major damage even if surrounding homes are destroyed. Americans know tornadoes like everyone else. The U.S. averages 1,200 twisters a year more than any other country on earth, and its intensity is notorious - at worst, it's a mile-wide, rotates at 300 mph and can plow at 70 mph. But despite the practice of being the target of these atmospheric power drills, American tornado mythology is still shrouded in mystery and misunderstanding. Given the stealthy nature of tornadoes, sudden appearance, erratic behavior, and short lifespans make them an inexplicable subject to study, but science has learned a lot in recent decades. Tornadoes can happen at any time of the year, but they are fighting an all-out war in the United States during spring and summer. With another tornado season already in full, below is a guide to how tornadoes work, when and where to expect them, and what you can do to bring it to life. Mesocyclones are often identifiable by rotating wall clouds, like this thunderstorm over Texas. NOAA tornadoes create the strongest winds on earth, but they have all their energy in the chaotic clouds that create them. Thunderstorms are common worldwide - 700-2,000 may be happening at any point - but became tough enough to form those tornadoes. However, it heats the water vapor until the sun rises, cools and condenses into a huge disturbance cloud, gradually collapsing on its own, leading to rain, hail and lightning. Thunderstorms alone are a severe force, but under certain conditions things can get even worse. Before a thunderstorm occurs, the wind begins to rapidly change speed and direction. If some gusts are redirected while already rising and accelerating, they can work with colliding air masses to help cause invisible horizontal vortices in the clouds. As rising air continues to feed the storm's growth, these upswells also tilt the vortex until it is vertical, sometimes trapped by its suction in the process. In a strong storm, it can stir up a wide rotating mass of low atmosphere known as a mesocyclone (pictured above), which can spread for miles. Mesocyclones make up the core of supercell thunderstorms. The consumption of warm, moist air in thunderstorms creates a vacuum effect that can remain behind extreme low pressure zones under clouds and pull the storm base until a wall cloud descends. If the storm is strong enough and the pressure is low enough, a rotating mesocyclone could also extend down a concentrated hypercharged funnel cloud known as a tornado. The tornado rotates violently as it raises the remaining humidity, a last-minute effort to keep thunderstorms going. When this quest for warm moisture results in a funnel in contact with the ground, it can be devastating for something or anyone in its way. Rope tornadoes meander to the ground. Craig Omille/Flickr It's no coincidence that America regularly surpasses 1,200 tornadoes a year — the middle part of the country is a sitting duck. North America's lack of east-west mountains allows it to move freely over continents where huge air masses from the Arctic, Southwest and Gulf of Mexico do energetically in spring and summer. The resulting collision over the Great Plains stirs up a storm named Tornado Alley. Oklahoma endures the most tornadoes of any state, but it has close company in Texas and Kansas. Tornado Alley has no official boundaries, but it essentially ranges from Appalachians to the Rocky Mountains and is at the core of high activity from South Dakota to central Texas. Dixie Alley, another U.S. region frequented by funnel clouds, embraces the Gulf Coast and is also powered by an outflow of warm, moist air. Florida is the most tornado-prone state outside tornado alleys thanks to near-daily summer thunderstorms. There is no true tornado season, but funnels usually start flying in late February or March, pick up steam in April and peak in May. Destructive tornadoes remain common through June and July, and some parts of the country experience a second mini-season in autumn, usually September. Tornadoes run in warm air and they usually occur in the afternoon or night, after heating enough air for the time of sun exposure to become unstable and ready to rise. The most common times for tornadoes are 5 .m. and then 6 and 7 p .m. These are the most frequently formed between 3 and 9 .m. The aftermath of a tornado in New Orleans. Mark Gustohl/Flickr Extreme wind speeds and suction make tornadoes a deadly threat, but the main risk for people is almost always flying debris and falling buildings. Tornadoes turn anything into missiles, often through building walls and throwing around various projectiles, and the ability to flatten cities in minutes is well known. If a tornado warning is issued (meaning a funnel cloud has been found nearby), evacuate immediately. (For more safety tips, see the Centers for Disease Control and Prevention's advice on tornado preparation.) Your main goal during a tornado is to avoid any flight or falling debris path that causes the most tornado-related deaths. If you are outside, it means getting low to the ground - and don't hide under bridges or overland bridges, collapse and actually wind can be faster. Don't try to overtake a tornado in your car, the CDC says. Go outside and find an open, treeless place that doesn't have many potential projectiles. Drop into ditches and other lowlands and protect your head with objects and your arms. If you are inside, the first rule is to avoid windows that are known to shatter under pressure from tornadoes. A strong tornado can crush an entire building, so the best place to wait for one is the basement or the interior part of the basement. If you can't go underground, head to the windowless central room, hallway, or closet on the bottom floor as much as possible. For extra safety, cover the sturdy ones like heavy tables and workbenches down. But if you're in a two-story building, think of what's upstairs - heavy objects like pianos and refrigerators can fall off. Mobile homes are the target of infamous tornadoes as they are easily overturned and torn apart by ferocious winds. The CDC and the Federal Emergency Management Agency recommend leaving your mobile home during a tornado warning, even if tied up. If you can reach one, head to the nearest basement or simply follow the rules to protect yourself outdoors. Even if the tornado disappears, the threat does not necessarily end. Many more could form, and even after the storm is over, the damage is at first-look risk - loose claws, broken glass and downed power lines are just some of the risks hidden in the rubble. For tips on what to do next, check out the CDC's After the Tornado guide. Here's a warning to turn down the sound to mute the videographer's response, as well as a video of several tornadoes operating:
